

Blazemeter With Taurus

- Introduction
 - What is Blazemeter and why is this our tool of choice for performance testing? [BlazeMeter | Documentation](#)
 - Taurus automation framework <https://gettaurus.org/>
- Installation
 - Setting up Taurus locally
 - [Click here to setup Taurus](#)
 - Blazemeter Chrome Extension plugin. [Click here to setup Blazemeter Chrome Extension plugin](#)
 - Setting up Helm and Kubernetes in order to run tests in our internal performance testing environment [Click here to setup Blazemeter with Kubernetes & Helm](#)
 - Accessing your Blazemeter account
 - [Accessing your Blazemeter account](#)
- Test organization

- Testing Strategies
 - Light to moderate load with before/after. This is our most common type of test
 - Automated Regression test in non production environments
 - Soak test
 - Load Test
 - Stress test
 - Geographical region test
- Protocol for production testing
- Common mistakes
 - Applying way too much load.
 - Always think in requests per second and not concurrent users. A website may have 300 concurrent users, but if they are idle, the requests/second will be low. This is typical of most Ascensus applications.
 - Not obtaining a big enough sample size for a test run. To filter out noise, you need an adequate amount of requests. For many APIs, this will be in the thousands.
 - Relying on status code 200 to determine if the http request was successful. Always have some type of assertion.
 - Not communicating when a production performance test will be performed. An RFC must be created and someone must go to the CAB meeting prior to running the performance test.
 - Running the production test from your local environment. Local is meant for development of the test only. Being on VPN will skew the results
 - Running a production test without devops or dba support. Always assume you may take down the system and be able to recover quickly.
 - Testing against a cache. Many of our applications are cached. I have seen performance tests run with one plan or one user, this will always give an inaccurate real world result if any caching is used.
