

Identity Provider (IDP) – QA & Automation Reference

**Purpose:**

This page serves as the parent reference for all QA and automation engineers working with the **Identity Provider (IDP)** system across **Stage** and **QC** environments.

It summarizes IDP's purpose, QA involvement, and the practical SQL tools used to validate, manage, and troubleshoot IDP accounts and MFA sessions.

What is IDP?

IDP (Identity Provider) is a central service responsible for **authentication, authorization, and user identity management** across the **Universal Platform (UP)** and **UNITE** systems.

It ensures:

- Secure login and session management
- MFA (PIN/2FA) validation
- Account provisioning and synchronization
- Password & profile consistency across applications

From a QA and automation standpoint, IDP acts as the **gateway microservice** between:

- **Universal Enrollment (UE)**
- **Sub-Bene**
- **UNITE** (legacy)
- **AWS-hosted Universal Platform**

IDP in QA & Automation Context

Component	QA/Automation Focus	Example Validation
IDP Login Flow	Validate authentication via API or UI; verify MFA trigger and session response.	Confirm AuthSession table logs correct SubjectId and PIN.
MFA (PIN Validation)	Retrieve, verify, and expire MFA PINs for test users.	Query Token.AuthSession for latest PIN.
Account Setup	Manage and reset user credentials during automation runs.	Update password, disable 2FA, or clear test accounts.
Data Sync / Migration	Confirm IDP correctly syncs user credentials with Universal Enrollment and UNITE.	Compare login results across environments.

Page Structure

Parent Page: Identity Provider (IDP) – QA & Automation Reference

Child Pages:

1. [IDP Account Setup & Maintenance \(SQL\)](#)
 - Managing IDP credentials, profiles, and account lifecycle.
 - Updating passwords, phone numbers, or MFA flags for test users.
2. [IDP MFA \(Multi-Factor Authentication\) Management \(SQL\)](#)
 - Retrieving or clearing MFA PINs.
 - Auditing PIN sessions and verifying cleanup logic.

Key QA Takeaways

- IDP bridges **authentication logic** between local and cloud applications.
- PIN-based MFA is **stored and cleared** in the Token.AuthSession table.
- Profiles, credentials, and MFA flags are managed in **person.Profile** and **person.Credential** tables.
- For performance and automation testing, **test accounts** are created and maintained in **Stage1** and **QC** databases.
- IDP enables **cross-environment validation**, ensuring credentials sync properly between **UNITE** and **Universal Platform**.

1. Document findings in test evidence under your **QA test cases (qTest / Confluence)**.
